A KeyMacro is a command or scripts in the Windows OS to execute a command or bash script on the Linux distribution that is installed as a subsystem. Main Features: There are several features that are directly related to the script execution. Executing commands on Linux with PowerShell Importing keymacros Local Linux scripts To summarize, there is a restriction for PowerShell with the execution of scripts and their arguments, which are normal Windows. To overcome this limitation, a keymacro was written and created by MSFT. The syntax is very simple, since you just need to add the commands as an argument to the parameters to the script. You can also set the arguments as local and global. Why It Is Needed The primary reason for developing a keymacro is to overcome PowerShell restrictions in executing scripts. Current restrictions PowerShell cannot execute a Bash shell script Solutions keymacro function Kerberos authentication Development Creating keymacros Notes As usual, you must be registered as a member of the group WSLTechSec. A keymacro with example The first thing you need to do is to download and import the keymacro function in your PowerShell. `import-module wsl [wsl.exe]::keymacro([string]$command)` WSL 1 `wsl.exe /rootinstall` WSL 2 `wsl.exe --install` Now, you can create your script as follows: `#Import wsl module [wsl.exe]::keymacro([string]$command)` #Create the script `.\do-bash-command.sh` #Execute & {`.\do-bash-command.sh`} If you want to execute the command that you set in the script using the argument ``-``, then you must do the following: `[wsl.exe]::keymacro([string]$command, $arg1)` #Create the script `.\do-bash-command.sh` #Execute & {`.\do-bash-command.sh`} -- \$arg1 In this case, the first argument, \$arg1, will be "--". After that, you can do the same as the first case: `[wsl.exe]::keymacro([string 1d6a3396d6`
